

In this codelab we learned than for use notifications in our app with need three basic methods `createNotificationChannel`, `getNotificationBuilder` and `sendNotification`

In create Notification channel we set the notify manager and we'll set all the property than we want in our notification like light, vibrate, etc

In get Notification Builder we going to create the builder who below to Notification compat, here we will set the icon, title, description, if we want to be auto cancel, the priority, the content intent, etc

In send Notification is pretty much just that, send the notification created with the get notification builder, we call `notify` from the builder, and we need to send inside the priority and the `notifyBuilder.build()`

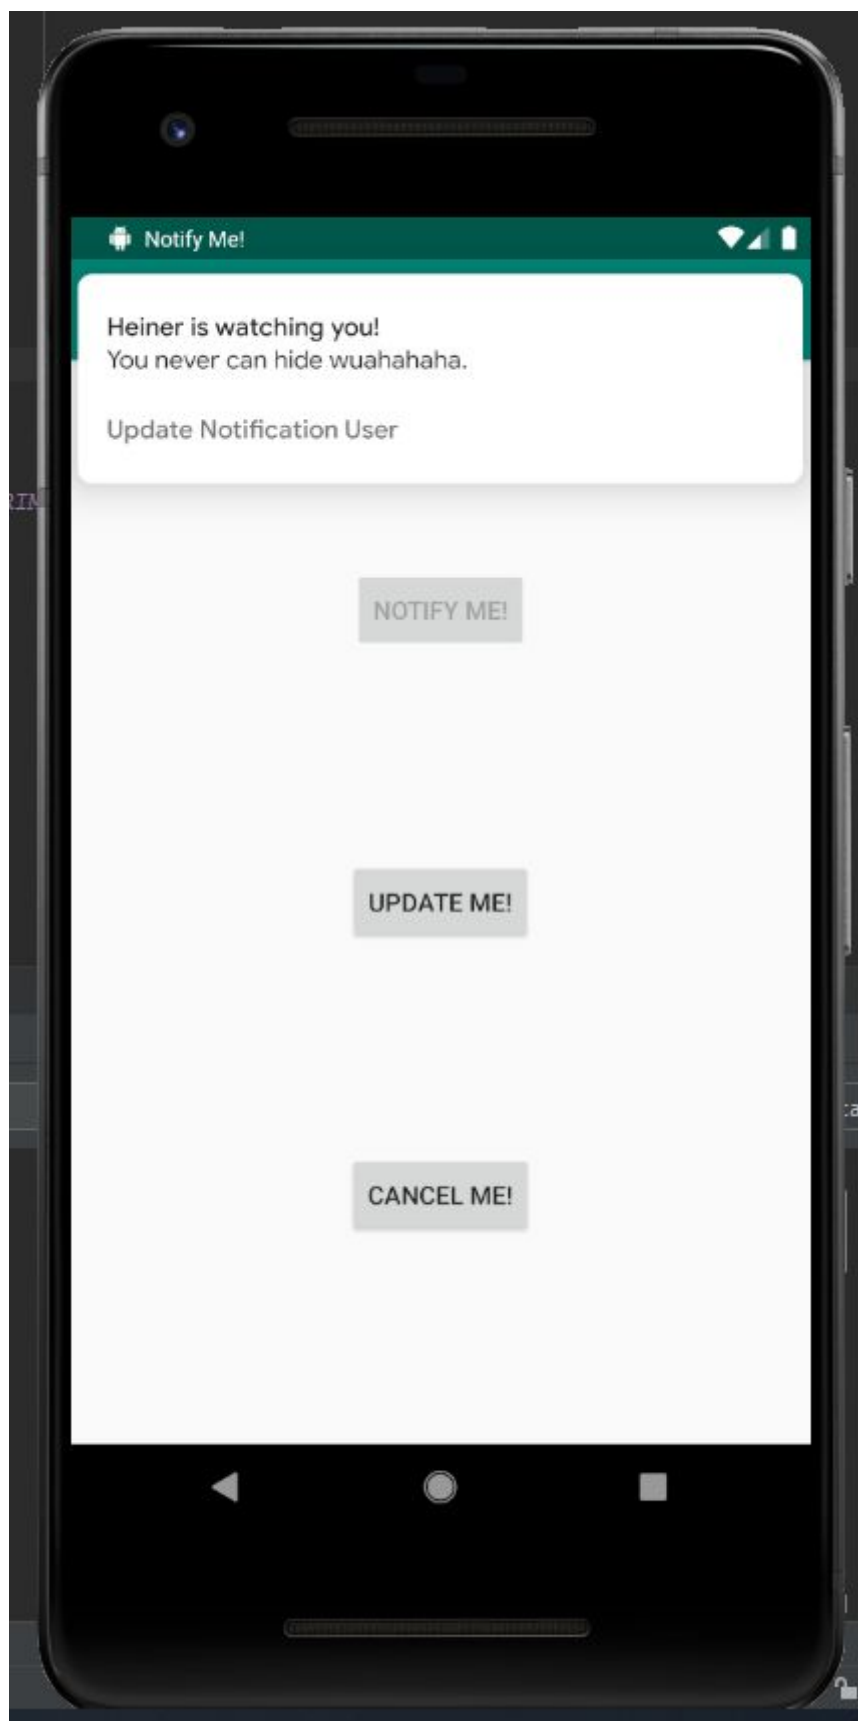

We learned then to cancel a notification in the app we just need to call the notification manager and call `cancel` and send inside the notification Id

We learned how to update notification in this case with use the subclass `BigPictureStyle`, for show a picture, so we need to cover a drawable to bitmap, this one can't have a width bigger than 420dp, we set the builder is we want to change the name we can but is not needed, and letter is just call `notify` again

To allow the user to update the notification when the app is in the foreground, we need to create broadcast receiver as we learned in the another codelab then in the `onReive` we need to call the method than we used to updated the notification

If we want to detect when the user clear the notification by itself we need to use the broadcast receiver, and add in the `notifyBuilder` the property `setDeleteIntent` in this one we are going to send a `Pendingintent` this one need to use `getBroadcast`, and remember to add the filter of this action in the `OnCreate` and for detecting which action the broadcast is receiving
